Nanoscale Control Systems

- **Sensing**
 - Reacting to forces
 - Binding to molecules
- **Actuating**
 - Releasing molecules
 - Producing forces
- **Constructing**
 - Chassis
 - Growth
- **Computing**
 - Signal Processing
 - Decision Making

Nucleic Acids can do all this.
And interface to **biology**.

Sensing

Aptamers: natural or artificially evolved DNA molecules that stick to other molecules (highly selectively).

Target molecule

Adenine riboswitch aptamer

Structural basis for discriminative regulation of gene expression by adenine- and guanine-sensing mRNAs. Chem Biol. 2004 Dec;11(12):1729-41.

Constructing

Crosslinking

Chengde Mao, Purdue

Andrew Turberfield, Oxford

Folding DNA into Twisted and Curved Nanoscale Shapes

Hendrik Dietz, Shawn M. Douglas, & William M. Shih
[Science, 325:725–730, 7 August 2009.](#)

Actuating

DNA tweezers

Bernard Yurke, Boise State

DNA walkers

Computing

- Sensors and Actuators at the 'edge' of the system
 - They can use disparate technologies and phenomena
- Computation in the 'kernel' of the system
- **Compositionality in the kernel**
 - The components should use uniform inputs and outputs
 - The components should be 'computationally complete'

“Embedded” Computing

- Using bacterial machinery (e.g.) as the hardware. Using embedded gene networks as the software.
- MIT Registry of Standard Biological Parts

- **GenoCAD**

- Meaningful sequences [Cai et al.]

r0040:prom; b0034:rbs; c0040:pcr; b0015:ter

- **GEC**

- [Pedersen & Phillips]

```
prom<neg (C)>; rbs; pcr<codes (A)>; ter;  
prom<neg (A)>; rbs; pcr<codes (B)>; ter;  
prom<neg (B)>; rbs; pcr<codes (C)>; ter
```

“Autonomous” Computing

- **Mix & go**
 - All (or most) parts are synthesized
 - No manual cycling (cf. early DNA computing)
 - In some cases, all parts are made of DNA (no enzyme/proteins)

- **Self-assembled and self-powered**
 - Can run on its own (e.g. environmental sensing)
 - Or be embedded into organisms, but running ‘separately’

Curing

A doctor in each cell

**Molecules and
computation**

Autonomous DNA Computing

Why Compute with DNA?

- Non-goals
 - Not to solve NP-complete problems.
 - Not to replace electronics.
 - Not necessarily using genes or producing proteins.
- For general ‘molecular programming’
 - To precisely control the organization and dynamics of matter and information at the molecular level.
 - To interact algorithmically with biological entities.
 - The use of DNA is “accidental”: no genes involved.
 - In fact, no material of biological origin.

Domains

- Subsequences on a DNA strand are called **domains**. *PROVIDED* they are “independent” of each other.

- I.e., differently named domains must not hybridize:
 - With each other
 - With each other's complement
 - With subsequences of each other
 - With concatenations of other domains (or their complements)
 - Etc.
- Choosing domains (subsequences) that are suitably independent is a tricky issue that is still somewhat of an open problem (with a vast literature). But it can work in practice.

Short Domains

Reversible Hybridization

Long Domains

Irreversible Hybridization

Strand Displacement

“Toehold Mediated”

Strand Displacement

Toehold Binding

Four-Domain Architecture

No “garbage collection”
(active waste removal)

DNA as a universal substrate for chemical kinetics

David Soloveichik^{a,1}, Georg Seelig^{a,b,1}, and Erik Winfree^{c,1}

PNAS | March 23, 2010 | vol. 107 | no. 12 | 5393–5398

Three-Domain Architecture

With garbage collection
(separate pass)

Strand Algebras for DNA Computing

Luca Cardelli

DNA Computing and Molecular Programming.
15th International Conference, DNA 15,
LNCS 5877, Springer 2009, pp 12-24.

“Lulu’s Trouble”

(from D.Soloveichik)

Two-Domain Architecture

- Signals: 1 toehold + 1 recognition region

Garbage collection
“built into” the gates

- Gates: “top-nicked double strands”
(or equivalently double strands with open toeholds)

Two-Domain DNA Strand Displacement

Luca Cardelli

In S. B. Cooper, E. Kashefi, P. Panangaden (Eds.):
Developments in Computational Models (DCM 2010).
EPTCS 25, 2010, pp. 33–47. May 2010.

Transducer $x \rightarrow y$

Transducer $x \rightarrow y$

Built by self-assembly!

ta is a *private* signal (a different 'a' for each xy pair)

Transducer $x \rightarrow y$

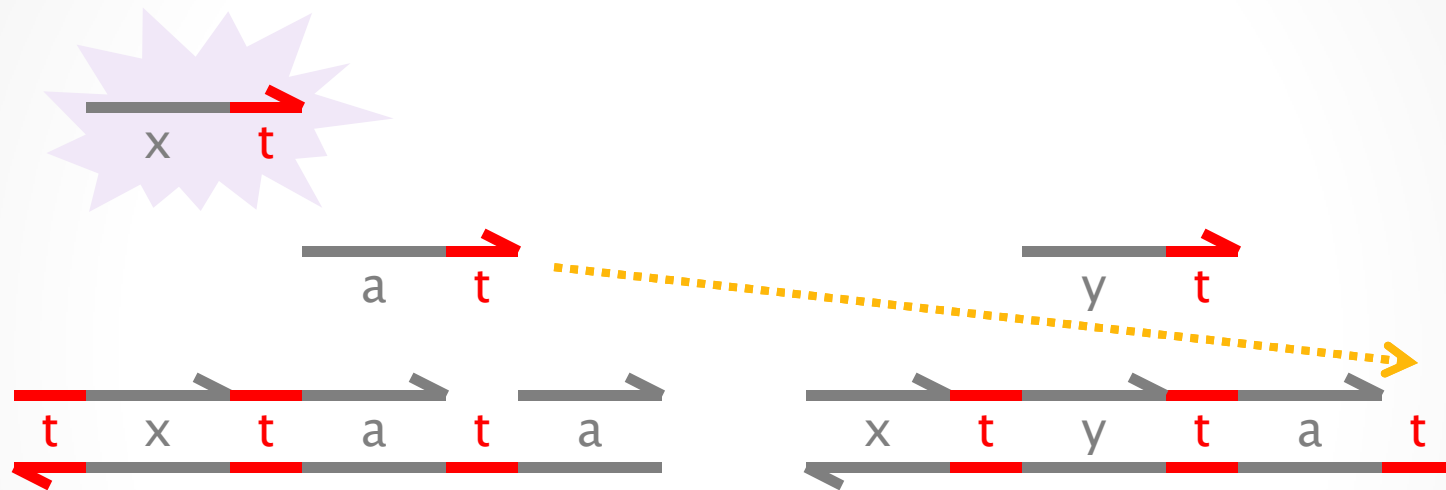

Transducer $x \rightarrow y$

Transducer $x \rightarrow y$

Transducer $x \rightarrow y$

So far, a tx *signal* has produced an at *cosignal*.
But we want signals as output, not cosignals.

Transducer $x \rightarrow y$

Transducer $x \rightarrow y$

Transducer $x \rightarrow y$

Transducer $x \rightarrow y$

Here is our output *ty signal*.

But we are not done yet:

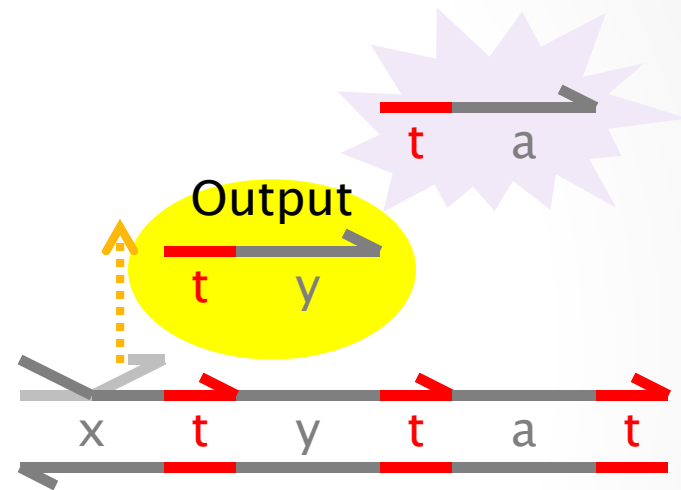

- 1) We need to make the output irreversible.
- 2) We need to remove the garbage.

We can use (2) to achieve (1).

Transducer $x \rightarrow y$

Transducer $x \rightarrow y$

Transducer $x \rightarrow y$

Transducer $x \rightarrow y$

Transducer $x \rightarrow y$

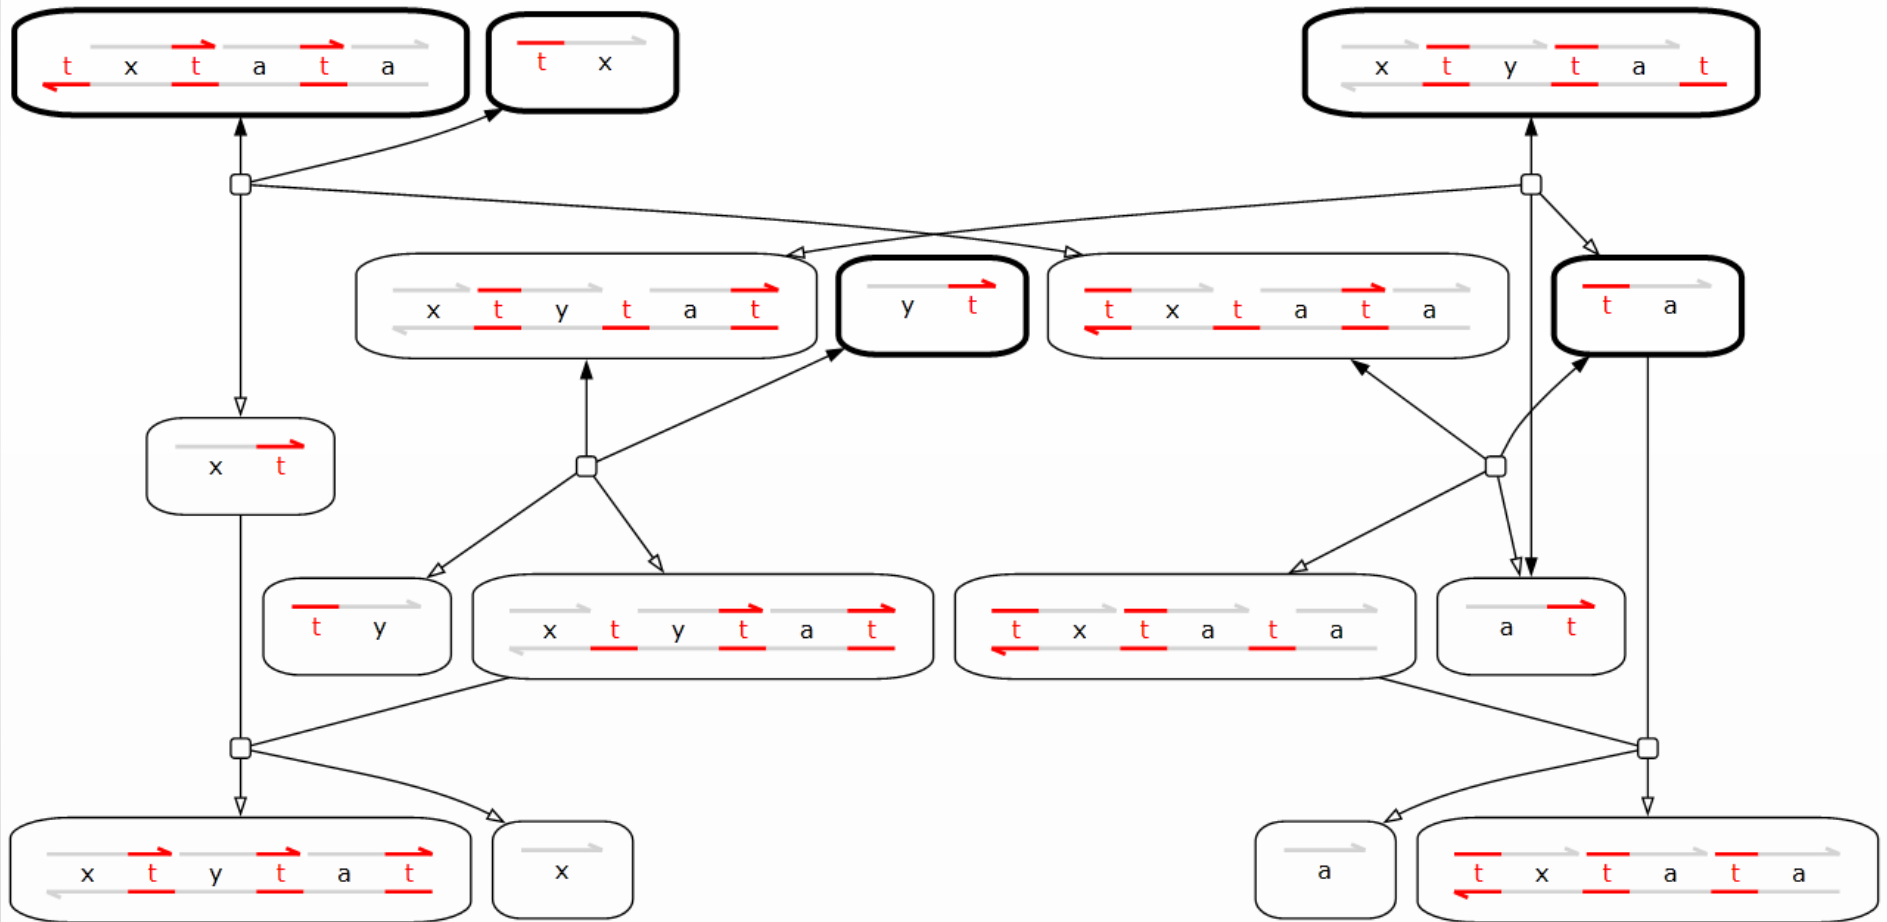

Transducer $x \rightarrow y$

Done.

N.B. the gate is consumed: it is the energy source.

Reaction Graph for $x \rightarrow y$

General $n \times m$ Join-Fork

- Easily generalized to 2+ inputs (with 1+ collectors).
- Easily generalized to 2+ outputs.

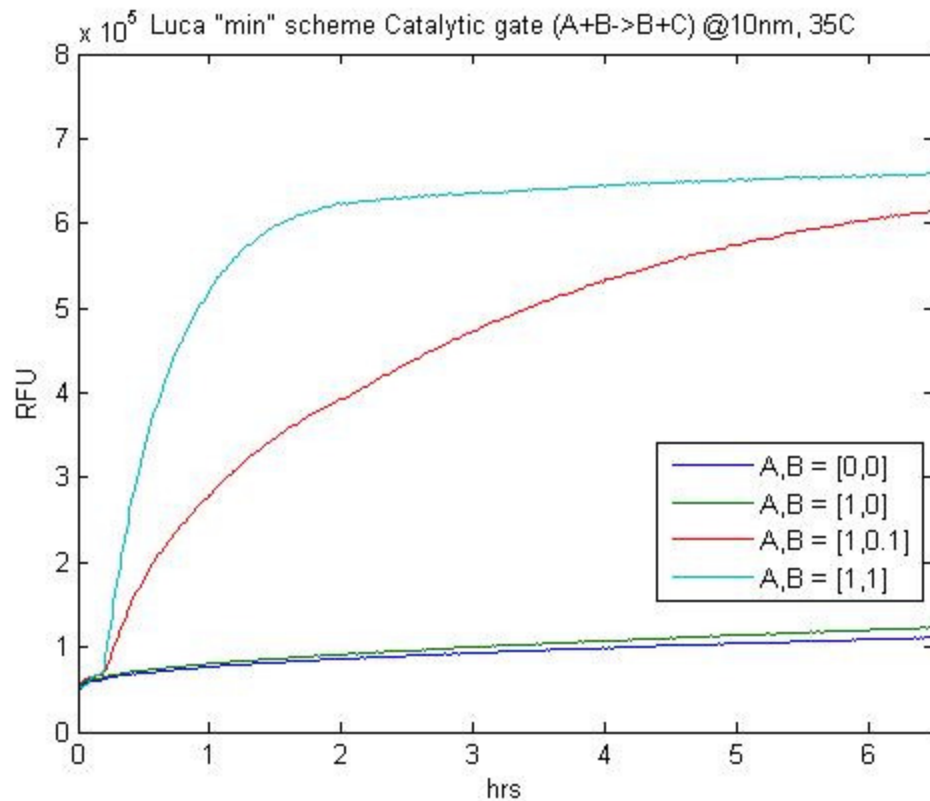

Figure 9: 3-Join $J_{wxyz} \mid tw \mid tx \mid ty \rightarrow tz$: initial state plus inputs tw, tx, ty .

Animations

- Animations

Experiments

Two-domain gate for $A+B \rightarrow B+C$

Matt Olson and Georg Seelig, U.Washington.

Experimental Challenges

- Quality of synthetic DNA
 - Chemical synthesis is limited in length and quality.
 - Two-domain scheme enables bacterial synthesis
 - Followed by enzyme digestion to introduce 'nicks'
 - Or nicking by a photosensitive artificial backbone
- Circuit optimization
 - Coming up with *simpler* systems for simplified experiments (shorter DNA sequences and smaller number of species)
 - Coming up with *faster* systems (more irreversible operations, and garbage collection).

Ex. Irreversible Output

Standard Transducer

Irreversible-output Transducer

Ex. Oscillator

- Three autocatalytic reactions

- This is a closed system

- (Or perhaps a performance-critical subsystem)

- Idea: use an optimized "internal" protocol that preserves the "public" interface of the system

- Use extra toeholds (instead of private domains) to connect the two halves of each gate (saving a domain).
- Trick: 1 extra toehold (instead of 3) is sufficient: there is a unique variable (x,y,z) connecting the two halves of gates.

Ex. Approximate Majority

- Four catalytic/autocatalytic reactions

- This is a closed system

- (Or perhaps a performance-critical subsystem)
- Same idea.

- But now 1 extra toehold is not sufficient (x and y catalyze two reactions). However 2 (instead of 4) toeholds are sufficient.

Verification Issues

- Environment

- The nano-environment is messy (stochastic noise, failures, etc.)
- But we should at least ensure our designs are *logically correct*

- Verifying Components

- Reversible reactions (infinite traces)
- Interferences (deadlocks etc.) between copies of the same gate
- Interferences (deadlocks etc.) between copies of different gates
- Removal of active byproducts (garbage collection) is tricky

- Verifying Populations

- Gates come in (large) populations
- Each population *shares private domains* (technologically unavoidable)
- Correctness of populations means proofs with large state spaces

Correctness

- The spec of a transducer:

$$x.y \mid x \rightarrow y$$

- Is it true at all?
- Is it true *possibly, necessarily, or probabilistically*?
- Is it true in the context of a *population of identical transducers*?
- Is it true *in all possible contexts*?
- If false, does it become true for *infinite populations*?

Interfering Transducers

- Let a be the private transducer domain, but let's share it between $x.y$ and $y.x$

- Interference: $x \cdot_a y \mid y \cdot_a x \mid x \not\Rightarrow^{\forall} x$

- But still: $x \cdot_a y \mid y \cdot_a x \mid x \mid y \rightarrow^{\forall} x \mid y$

- A large population of such gates in practice does not deadlock easily.

- **The wisdom of crowds**: individuals can be wrong, but the population is all right.

Stuck gates in
a population
of 200

Modelchecking DNA Systems

- Using the PRISM stochastic modelchecker
 - Termination probability of interfering transducers
 $x \mid x \cdot_a y \mid y \cdot_a z$

L. Cardelli, M. Kwiatkowska, M. Lakin, D. Parker and A. Phillips.
Design and Analysis of DNA Circuits using Probabilistic Model Checking.
<http://qav.comlab.ox.ac.uk/papers/dna-pmc.pdf>. September 2010

Conclusions

Summary

- **Molecular Structures**
 - Hard to build... but they can build themselves!
- **Molecular Languages**
 - Natural and unnatural
 - Concurrent, quantitative
- **Molecular Compilation**
 - Molecular architectures, verification, optimization
- **Molecular Programming**
 - In silico, in vitro, in vivo...
